FOREWORD

As the temperature of thermal sources is increased, a region (kT > 2 kev) is encountered in which transport of the emitted photons (of the order of 10 - 500 kev) through low and medium atomic number materials is determined by other than photoelectric absorption only. Recent Kaman Nuclear reports include pertinent discussions, but it was considered useful to generalize and extend this work and to collect working equations and graphs under one cover. This paper briefly discusses the phenomenology of Compton and Rayleigh scattering, establishes working equations, provides tables of scattering data, displays graphs of equations and data in the photon energy range from one to one-thousand kev, discusses the effect of scattering on x-ray transport, and suggests general methods of solution of the multiple scattering problem.

ABSTRACT

Compton and Rayleigh scattering for x-rays in the range of 10 to 1000 kev is described, and equations, data, and graphs are presented. Effects of scattering on transport are discussed, and methods of solving the multiple scattering transport problem are suggested.

LIST OF SYMBOLS

E	recoil electron kinetic energy
h	Planck's constant

X-RAY TRANSPORT - I (SCATTERING)

1. Introduction

In the transport of x-rays through matter, there are three dominant mechanisms of interaction. These are the photoelectric effect, the Compton effect, and pair production, having domains of relative dominance as shown in Figure 1.

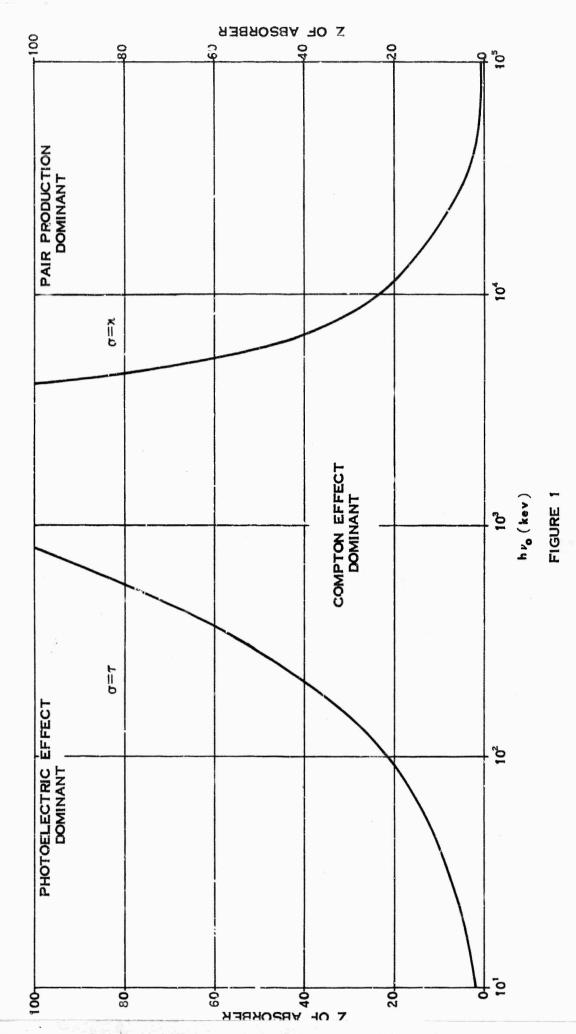

The region of interest here is 10 < $h\nu_{_{\rm O}}$ < 1000 kev where pair production may be neglected. Other less dominant effects have been shown to be unimportant² except for the Rayleigh effect which will be considered below. Also, the Compton effect³ is discussed in terms of its three components: (1) absorption, (2) inelastic scattering from free electrons, and (3) inelastic scattering from bound electrons.

2. Compton Free Electron Inelastic Scattering Relationships

Assuming a stationary electron, the recoil electron kinetic energy E greater than the electron binding energy $B_{\rm e}$, and applying the laws of conservation of relativistic energy and momentum to the situation in Figure 2.

One obtains for the scattered photon wavelength shift

$$\lambda' - \lambda_{O} = (h/m_{O}c) \quad (1 - \cos \theta) \tag{1}$$

DOMAINS OF DOMINANCE OF . - RAY ATTENUATION MECHANISMS

COMPTON SCATTERING (FREE ELECTRON - INCOHERENT)

$$\lambda' - \lambda_o = (h/m_o c) (1 - \cos \theta)$$

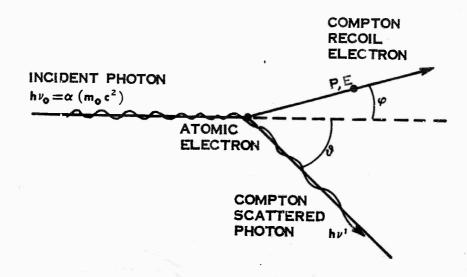

FIGURE 2

COMPTON SCATTERING OF A PHOTON BY AN ELECTRON

and for the scattered photon energy, using $\alpha = h\nu_0/m_0c^2$,

$$h\nu' = h\nu_0[1 + \alpha(1 - \cos \theta)]^{-1}$$
 (2)

which is plotted in Figure 3 for 10 < $h\nu_0$ < 1000 kev. Equation 2 determines the energy $h\nu'$ of a photon of incident energy $h\nu_0$ scattered at an angle 9.

The recoil electron direction, φ , is related to θ and α by

$$\cot \varphi = (1 + \alpha) \tan (\theta / 2) \tag{3}$$

which is shown in Figure 4.

Recoil electron kinetic energy is given by

$$E = h_{\nu_0} - h_{\nu'} = h_{\nu_0} \alpha (1 - \cos \theta) / [1 + \alpha (1 - \cos \theta)]$$
 (4)

and is plotted in Figure 5. This may be expressed in terms of ϕ using Equation (3).

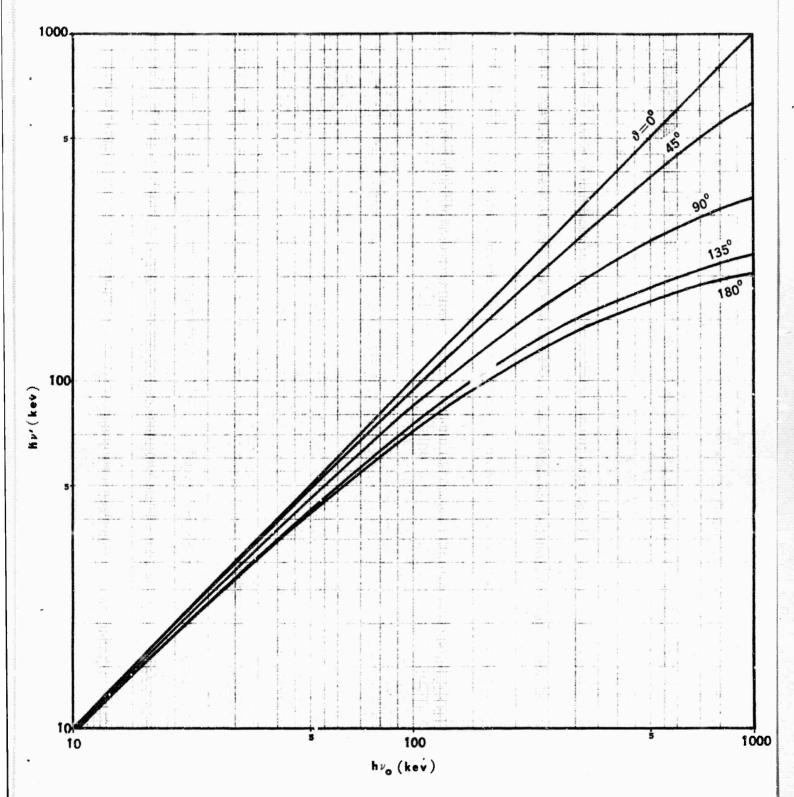

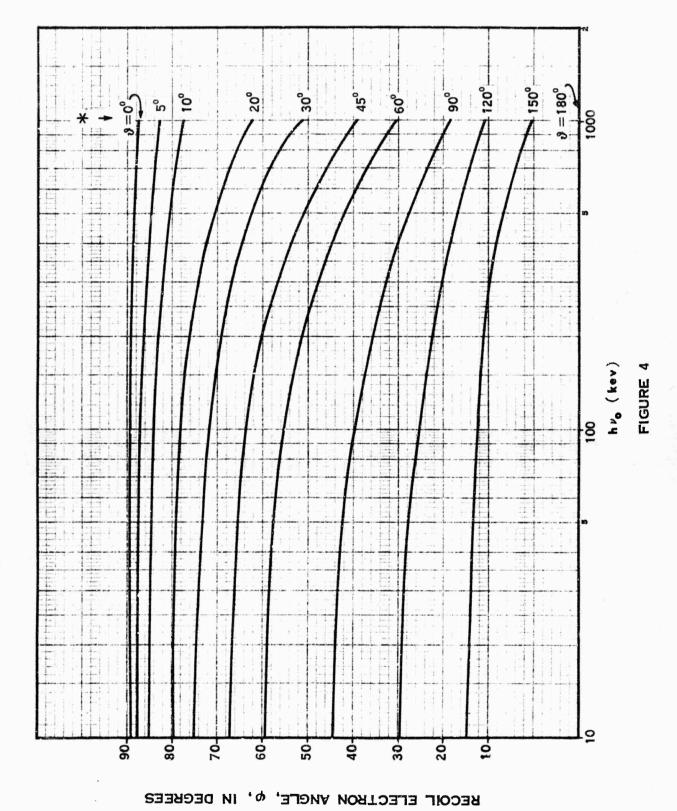

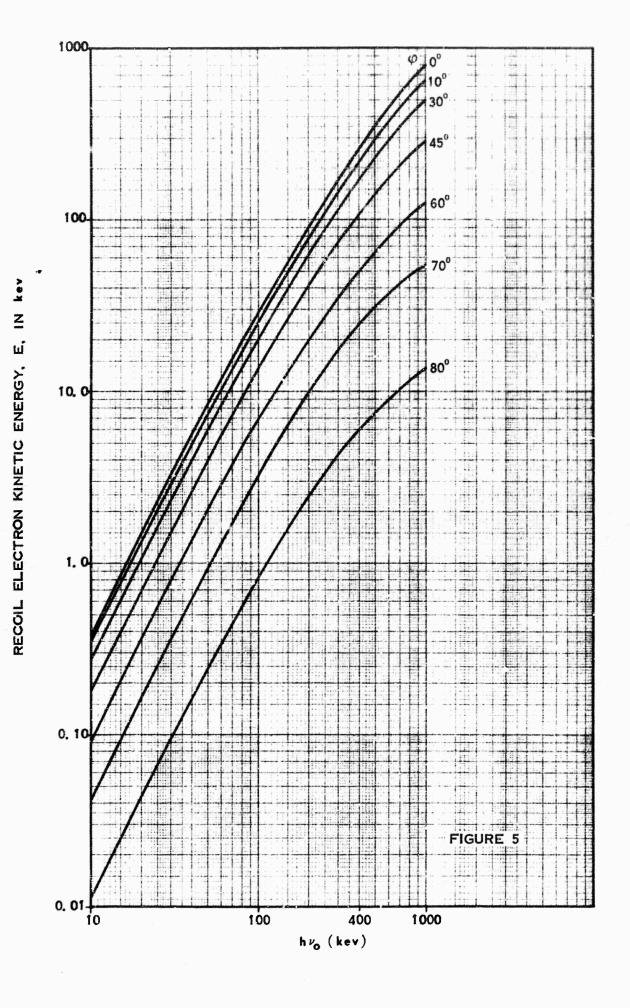

FIGURE 3

3. Compton Free Electron Inclantic Scattering Cross Sections

When photoin delilde with electrons, the number of photons montered in a particular direction may be described by a dif-

$$d(ge) = \frac{11}{10010ent} \frac{gast tered}{fnumber/ome} \frac{1}{20000ent} \frac{1}{10010ent} \frac{1}{10010ent$$

The amount of a southered in a particular direction may be given by a differential southering cross section per electron

$$d(_{e}\sigma_{B}) = \frac{\text{energy scattered/sec (erg/sec-electron)}}{\text{incident intensity (erg/cm}^{2}\text{-sec)}}, (6)$$

and the amount of energy absorbed by the electron may be given by the differential absorption cross section per electron

$$d(e^{\sigma_a}) = \frac{\text{energy absorbed/sec (erg/sec-electron)}}{\text{incident intensity (erg/cm}^2 - \text{sec})}.$$
 (7)

These are related as follows [and shown in Figure (6)]:

$$d(_{e}\sigma) = d(_{e}\sigma_{g}) + d(_{e}\sigma_{g}) , \qquad (8)$$

$$d(_{e}\sigma_{s}) = \frac{\nu'}{\nu_{o}} d(_{e}\sigma) , \qquad (9)$$

and

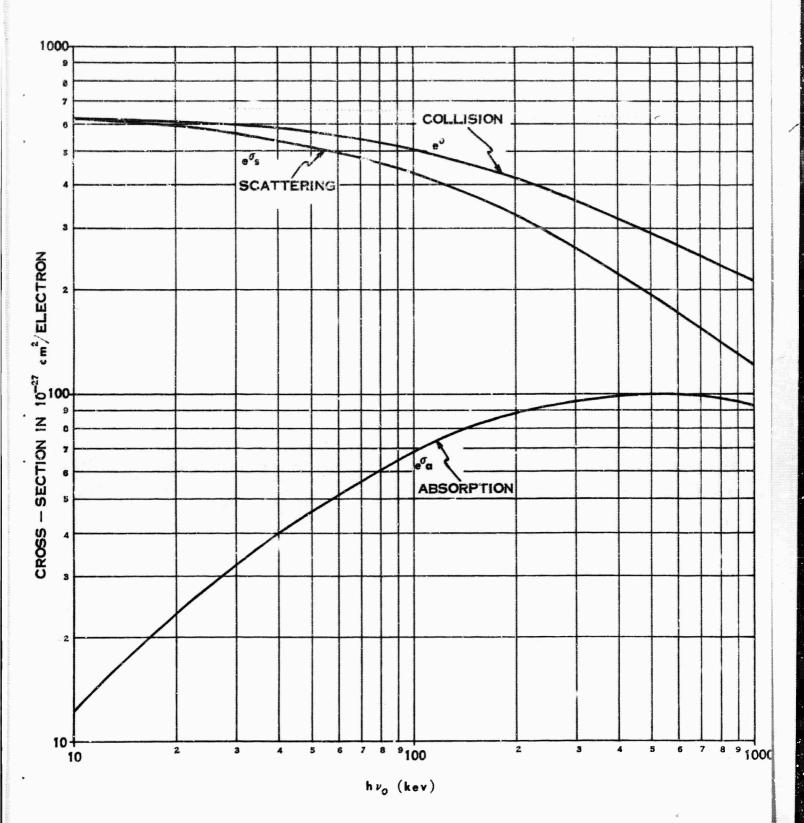

FIGURE 6

KLEIN - NISHINA CROSS SECTIONS,
DEPENDENCE ON INCIDENT ENERGY

$$d(_{e}\sigma_{a}) = \frac{\nu_{o} - \nu'}{\nu_{o}} d(_{e}\sigma) = \frac{\nu_{o} - \nu'}{\nu'} d(_{e}\sigma).$$
 (10)

The differential cross sections per atom are obtained by multiplying by the atomic number Z of the material, e.g.,

$$d(a\sigma) = Z d(e\sigma) . (11)$$

Explicitly, the differential collision cross section for incident unpolarized radiation derived by Klein and Nishina 4 is given by

$$d(_{e}\sigma) = r_{o}^{2} d\Omega \left\{ 1/[1 + \alpha(1 - \cos \theta)]^{2} \right\} [(1 + \cos^{2}\theta)/2]$$

$$[1 + \left\{ \alpha^{2}(1 - \cos^{2}\theta)^{2}/(1 + \cos^{2}\theta) [1 + \alpha(1 - \cos\theta)] \right\}] \qquad (12)$$

where $r_0 = e^2/m_0 c^2 = 2.818 \times 10^{-13}$ cm and $d\Omega = differential$ element of solid angle at θ into which photons are scattered. This equation is known to agree well with experiments up to $\alpha \cong 600$. For small α it reduces to the Thomson scattering equation. From Equations (8), (9), (10), and (11), one may obtain explicit forms for $d(e^{\sigma})$, $d(e^{\sigma})$, $d(e^{\sigma})$, and $d(e^{\sigma})$. From

$$d\Omega = 2\pi \sin \theta \ d\theta \tag{13}$$

we have

$$d(_{e}\sigma) / d\theta = 2\pi \sin \theta d(_{e}\sigma) / d\Omega,$$
 (14)

which gives the probability per incident photon per electron per cm 2 of material that the scattered photon will be directed between θ and θ + $d\theta$. This is shown in Figure 7.

Using Equations (3) and (13), the number of electrons recoiled into $\mathrm{d} \varphi$ at φ may be written

$$d(_{e}\sigma)/d\varphi = [d(_{e}\sigma)/d\Omega] [2\pi(1 + \cos \theta) \sin \varphi]/(1 + \alpha) \sin^{2} \varphi. (15)$$

Cross sections giving the probability of an event occurring so that a photon is scattered into a restricted angular region may be determined from the integrals of the differential cross sections; e.g.,

$$e^{\sigma} (\theta_{\ell} \leq \theta \leq \theta_{u}) = \int_{0}^{\theta_{u}} [d(e^{\sigma}) / d\Omega] d\Omega.$$
 (16)

Values for $(0 \le \theta \le \theta_u)$ are plotted in Figure 8, from which much useful information may be obtained, such as:

- (1) the number of photons scattered into the interval $\theta_1 \le \theta \le \theta_2$ corresponds to $e^{\sigma(\theta_2)} e^{\sigma(\theta_1)}$,
- (2) the collision cross section for forward scattering is ${\rm e}^{\sigma(\le \pi \ /\ 2)} \ {\rm and} \ {\rm for\ backward\ scattering\ is} \ {\rm e}^{\sigma(\le \pi \ /\ 2)} \ {\rm e}^{\sigma(\le \pi \ /\ 2)},$

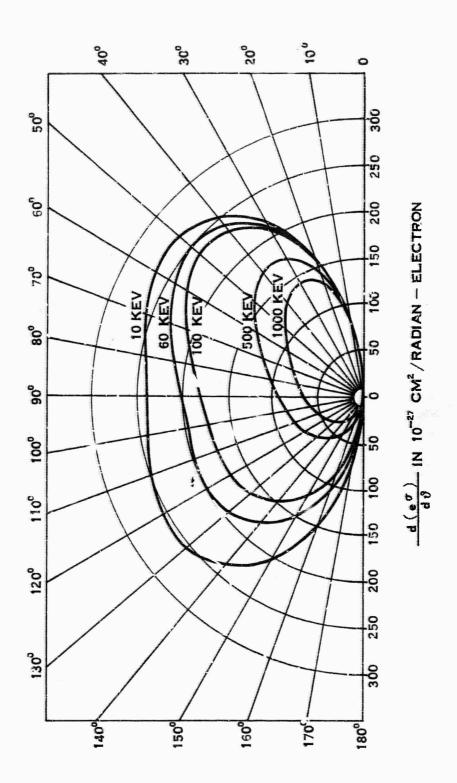

FIGURE 7

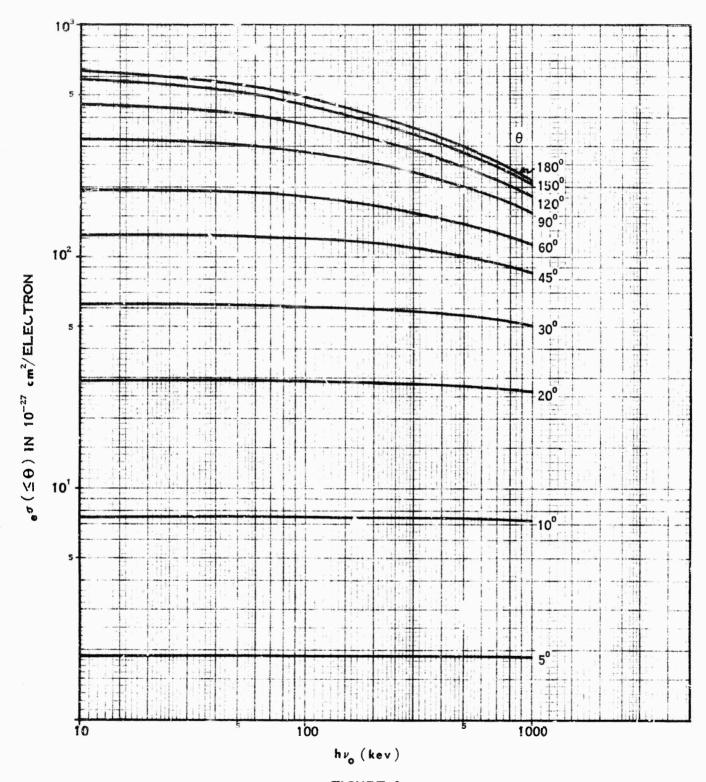

FIGURE 8

- (3) the number of recoil electrons scattered into $\varphi_1 \leq \varphi \leq \varphi_2$ is read from Figure 8 after using Equation (3), or Figure 4,
- (4) the number of photons scattered between θ_1 and θ_2 is the number of electrons scattered between φ_1 and φ_2 where the angles are related by Equation (3), and
- (5) the fraction of scattered photons with more than an arbitrary energy is obtained in conjunction with Figure 3. For example, what fraction of 100 kev photons have energy greater than 80 kev? From Figure 3, $\theta \le 100^{\circ}$; and from Figure 8, $e^{\sigma} (\le 100^{\circ}) = 320$ and $e^{\sigma} (\le 180^{\circ}) = 500$; thus, the fraction is 320/500 = .64.

One also may obtain, from Equation (16), the average (total over-all scattering angles) collision cross section per electron, which is the probability of removal of a photon from a collimated beam while passing through an absorber with one electron/cm²,

$$e^{\sigma} = \int_{0}^{\pi} d(e^{\sigma})$$

$$= 2\pi r_{0}^{2} \left\{ \frac{1 + \alpha}{\alpha^{2}} \left[\frac{2(1 + \alpha)}{1 + 2\alpha} - \frac{\ln(1 + 2\alpha)}{\alpha} \right] + \frac{\ln(1 + 2\alpha)}{2\alpha} - \frac{(1 + 3\alpha)}{(1 + 2\alpha)^{2}} \right\}$$
(17)

which, for $\alpha <<$ 1 becomes

$$e^{\sigma} \approx (8\pi r_0^2/3) \left[1 - 2\alpha + (26\alpha^2/5) - (133\alpha^3/10) + \frac{114\mu}{35}\alpha^4 + \dots\right].$$
 (18)

For $\alpha \leq 0.2$ terms up to α^3 are sufficient for 5% accuracy.

For $\alpha >> 1$, Equation (17) becomes

$$e^{\sigma} = \pi r_0^2 \left(1 + 2 \ln 2\alpha\right) / 2\alpha . \tag{19}$$

Similarly,

$$e^{\sigma_{S}} = \pi r_{o}^{2} \left[\frac{\ln(1+2\alpha)}{\alpha^{3}} + \frac{2(1+\alpha)(2\alpha^{2}-2\alpha-1)}{\alpha^{2}(1+2\alpha)^{2}} + \frac{8\alpha^{2}}{3(1+2\alpha)^{3}} \right].$$
(20)

From these, one may obtain the average energy per scattered photon, $(h\nu')_{av}$, as the energy scattered in all collisions divided by the number of collisions; i.e.,

$$(h_{\nu})_{av} = (h_{\nu_0}) e^{\sigma_s/e^{\sigma_s}}. \tag{21}$$

Using Equations (21) and (4), one obatins the average energy of the recoil electrons, \mathbf{E}_{av} .

Also, one may write, using Equations (12), (13), and (2), the number of photons scattered into dh_{ν} ' at h_{ν} ' as

$$\frac{d(e^{\sigma})}{dh_{\nu}!} = \frac{d(e^{\sigma})}{d\Omega} \frac{d\Omega}{d\theta} \frac{d\theta}{dh_{\nu}!}$$

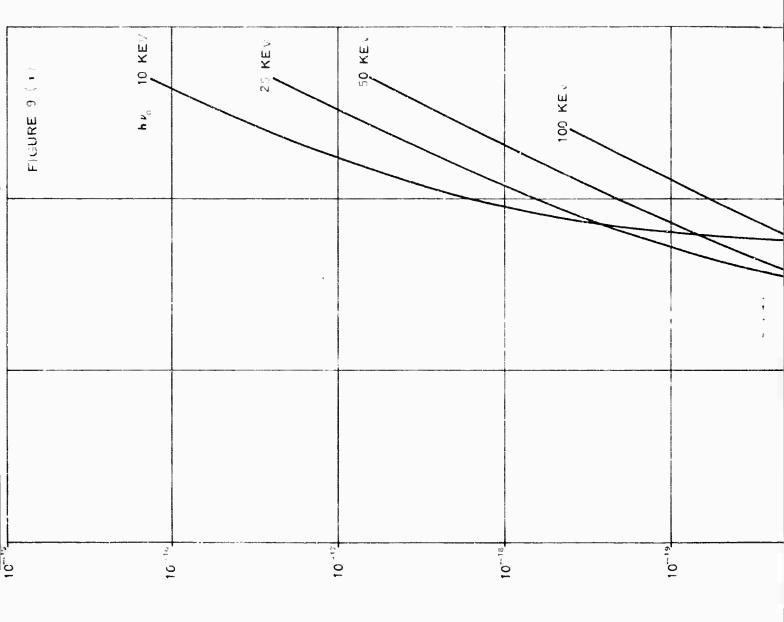

$$= (\pi r_0^2 / \alpha^2 m_0^2) \left\{ 2 + (\frac{h_{\nu_0} - h_{\nu'}}{h_{\nu'}})^2 \left[\frac{1}{\alpha^2} + \frac{h_{\nu'}}{h_{\nu_0}} - \frac{2}{\alpha} (\frac{h_{\nu'}}{h_{\nu_0} - h_{\nu'}}) \right] (22) \right\}$$

or in terms of α ,

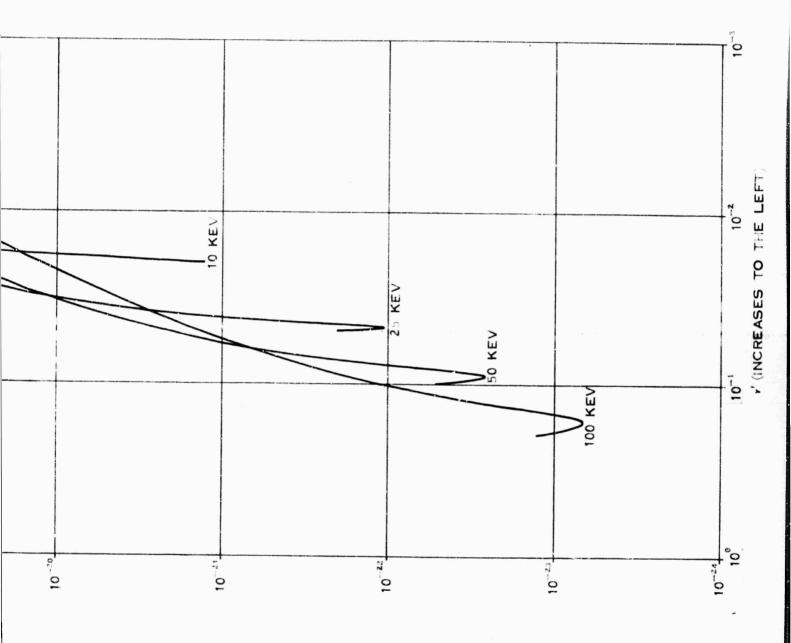

$$d(e^{\sigma)}/d\alpha' = (\pi r_0^2/\alpha^2) \left\{ (\alpha/\alpha') + (\alpha'/\alpha) - 2[(1/\alpha') - (1/\alpha)] + [(1/\alpha') - (1/\alpha)]^2 \right\}$$
(22)

which is plotted in Figure (9).

Various cross sections per electron and average energies are listed below in Table I.

 $(v, d\alpha) = cm^2 / ELECTRON$

4. Compton Bound Electron Inelastic Scattering

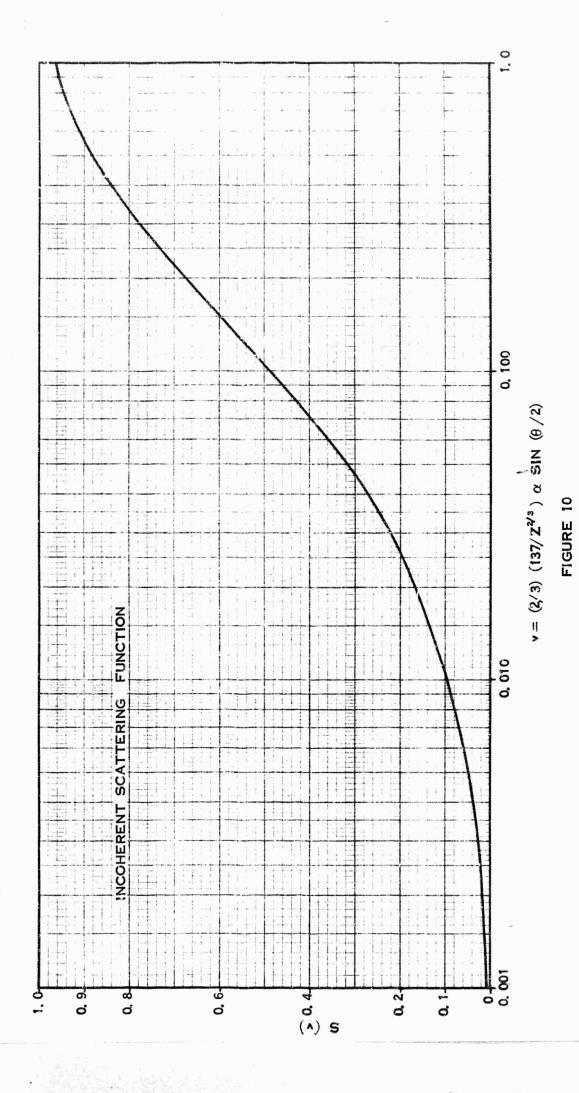

From Table I, we see that for low h_{ν_0} the average electron recoil energy becomes of the order of B_e , and the free electron assumption of the Compton effect derivation may be violated. This and the initial momentum an electron has in an atom results in a small shift of h_{ν} ' and $(\lambda^{!} - \lambda_{0})$ which we will neglect. More importantly, electron binding affects the differential collision cross section because it introduces a probability that the electron will not be recoiled from the atom but excited to a different bound energy level instead. The mutually independent probabilities of collision, and either recoil or excitation results in a total differential incoherent collision cross section given by

$$d(e^{\sigma_{incoh}}) / d\Omega = [d(e^{\sigma}) / d\Omega] S$$
 (23)

where S = S(h ν_0 , Z, 9) is the incoherent scattering function^{5,6} which may be expressed⁷ as a function of a parameter v where

$$v = (2/3) (137/Z^{2/3}) (\alpha) \sin(9/2) = (4\pi/3)(\alpha_0/\lambda)(1/Z^{2/3})\sin(9/2).$$
(24)

Of the various approaches to an analytical expression for S, we select here that derived^{5,6} on the Thomas-Fermi atomic model plotted in Figure 10 and given by the empirical equation

$$S = 1 - e^{-4.875}v^{0.8559}$$
 (25)

to within 10% accuracy.

5. Rayleigh Elastic Scattering

For sufficiently small incident photon energy compared to the electron's binding energy there is too little energy transferred to the electron to produce recoil or excitation. The entire atom absorbs the photon momentum and the scattered radiation has no wavelength shift. All electrons in an atom act similarly so scattering from electrons in the same atom is in phase or coherent and in the low energy limit becomes classical Thomson scattering. (If many atoms are in an ordered arrangement, the scattering is called Bragg reflection.) This may be treated like Compton bound electron scattering by modifying the Thomson differential coherent scattering (no absorption) cross section by an atomic structure factor, if, getting

$$d(a\sigma_{coh})\Delta\Omega = (r_o^2/2) (1 + cos^2 \theta) F^2$$
, (26)

where $F = F(h_{\nu_0}, Z, \theta) = F(u)$ and

$$u = 2(137/3^{1/3}) \alpha \sin(\theta/2) = 4\pi(a_0/\lambda)(1/2^{1/3}) \sin(\theta/2).$$
 (27)

Figure 11 shows F/Z taken from Nelms and Oppenheim 11, from which the empirical expression

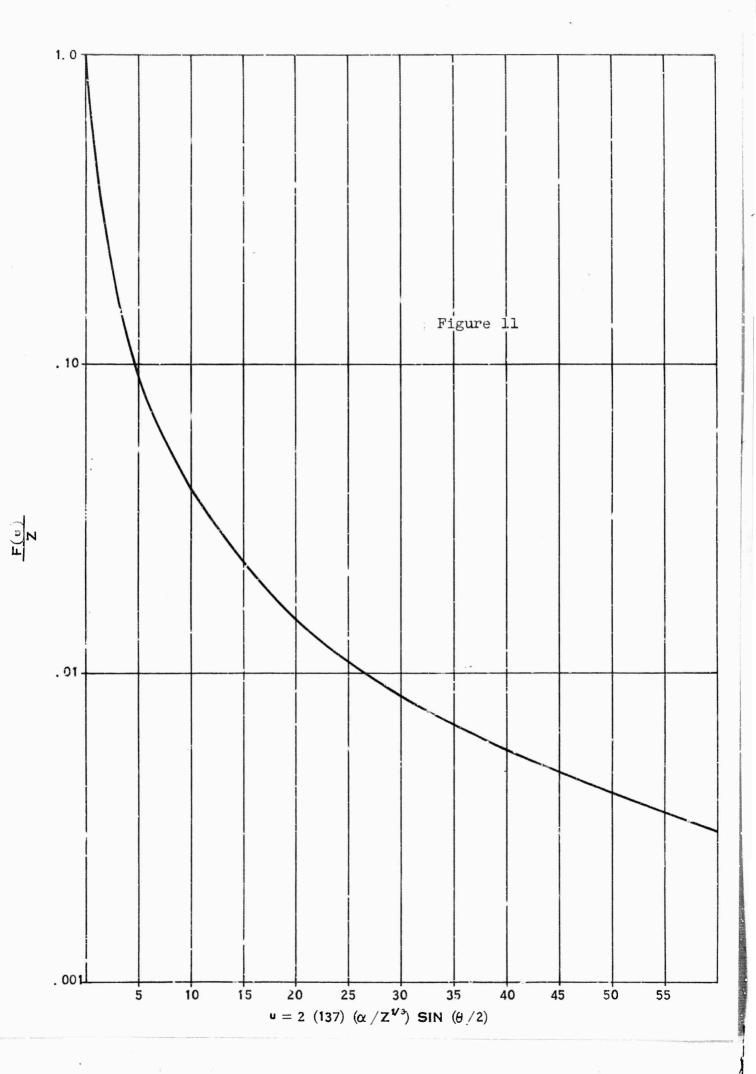

$$F/Z = e^{-1.488u^{0.3884}} (1 + u^{-0.2998}) + 3.266 \times 10^{-3}$$
 (28)

has been computed accurate to within 10%.

6. Photon Transport, Build-Up, and Distribution

Transport through a medium may result in an accumulation of primary direct photons and secondary scattered photons at a point of interest. The ratio of the number of primary plus secondary photons to the number of primary photons at a point is called the build-up factor B.

Upon Compton scattering, the scattered photon has lower energy and is more susceptible to further "energy loss" by additional Compton scattering or photoelectric absorption. A Rayleigh scattered photon has a large probability of being Compton scattered or photoelectrical y absorbed upon further collision. An increase in the probability of collisions by an increase in dimension or density of the transport material, therefore, degrades the energy spectrum to lower values, spreads the time of arrival of photons, distributes the directions of arrival of photons, and changes B.

If the transport medium geometry (actually distance multiplied by density, $\rho d)$ is small compared to photon mean free paths or if only narrow photon beams are considered, then for attenuation the usual exponential expression is used with the attenuation coefficient consisting or $\sigma^{PE} + \sigma^{C} + \sigma^{R}$ with σ^{C} modified for bound electrons 12 . For energy deposition the absorption coefficient $\sigma^{PE} + \sigma_{a}^{C}$ with σ_{a}^{C} modified for bound electrons 12 is used. In either case, corrections for fluorescence in high Z materials and Bremsstrahlung at high energies should be considered 13 .

When the transport medium od is of the order of mean free paths or when the medium has finite thickness but infinite extent so that only a few successive scatterings occur, one may apply the scattering equations the appropriate number of times 14 using the Compton collision or absorption coefficients for attenuation or deposition, respectively. However, if the mean free path of the scattered photon is less than od, the probability of its being absorbed before escaping the medium is increased so that for energy deposition the absorption coefficient is only a lower limit while the attenuation coefficient is an upper limit. For od much larger than the collision mean free path of the scattered photon, the attenuation coefficient would be used for energy deposition as well as attenuation.

When ρd is sufficiently large for multiple scattering to occur, simple multiple application of the above equations becomes inordinately complicated and solutions to the problem of photon build-up and distribution must be obtained from other methods such as a statistical study of scattering of many photons or the more general transport theory. ¹⁴

Inherent difficulties and inaccuracies in approximate solutions of the general transport theory limit its practical usefulness, therefore, statistical methods such as the Kaman Nuclear Monte Carlo Gamma Ray Transport Code 15 written for the IBM 7090 Computer and recently adapted for x-rays 2 are more popular for practical calculations of photon build-up and distribution resulting from scattering.

A report describing the Monte Carlo computations and including results for air transport, is in preparation.
